ADVANCED COMMUNITY DATA ANALYSIS USING VEGAN

Gavin L. Simpson ESA 2015 · Aug 9th 2015

CONSTRAINED ORDINATION

CANONICAL CORRESPONDENCE ANALYSIS

CCA is the constrained form of CA; fitted using cca().

Two interfaces for specifying models

- basic; cca1 <- cca(X = varespec, Y = varechem)</pre>
- formula; cca1 <- cca(varespec ~ ., data = varechem)</pre>

Formula interface is the more powerful — recommended

CANONICAL CORRESPONDENCE ANALYSIS

```
cca1 <- cca(varespec ~ ., data = varechem)</pre>
cca1
Call: cca(formula = varespec \sim N + P + K + Ca + Mg + S + Al + Fe +
Mn + Zn + Mo + Baresoil + Humdepth + pH, data = varechem)
           Inertia Proportion Rank
Total
         2.0832 1.0000
Constrained 1.4415 0.6920 14
Unconstrained 0.6417 0.3080 9

```

REDUNDANCY ANALYSIS

RDA is the constrained form of PCA; fitted using rda().

```
rda1 <- rda(varespec ~ ., data = varechem)
rda1
Call: rda(formula = varespec ~ N + P + K + Ca + Mg + S + Al + Fe +
Mn + Zn + Mo + Baresoil + Humdepth + pH, data = varechem)
             Inertia Proportion Rank

```

THE cca.object

- · Objects of class "cca" are complex with many components
- Entire class described in ?cca.object
- Depending on what analysis performed some components may be **NULL**
- Used for (C)CA, PCA, RDA, and CAP (capscale())

THE cca.object

cca1 has a large number of components

- **\$call** how the function was called
- \$grand.total in (C)CA sum of 'rowsum}
- **\$rowsum** the row sums
- **\$colsum** the column sums
- **\$tot.chi** total inertia, sum of Eigenvalues
- **\$pCCA** Conditioned (partialled out) components
- **\$CCA** Constrained components
- **\$CA** Unconstrained components
- · \$method Ordination method used
- **\$inertia** Description of what inertia is

THE cca.object

Depending on how one called cca() etc some of these components will be NULL

\$pCCA is only filled in if a *partial* constrained ordination fitted

rda() returns objects with classes "rda" and "cca", but in most cases those objects work like those of class "cca"

The Eigenvalues and axis scores are now spread about the \$CA and \$CCA components (also \$pCCA if a partial CCA)

Thankfully we can use extractor functions to get at such things

/

EIGENVALUES

eigenvals(cca1)

Use eigenvals() to extract Eigenvalues from a fitted ordination object

```
CCA1 CCA2 CCA3 CCA4 CCA5 CCA6 CCA7
0.4388704 0.2917753 0.1628465 0.1421302 0.1179519 0.0890291 0.0702945
CCA8 CCA9 CCA10 CCA11 CCA12 CCA13 CCA14
0.0583592 0.0311408 0.0132944 0.0083644 0.0065385 0.0061563 0.0047332
CA1 CA2 CA3 CA4 CA5 CA6 CA7
0.1977645 0.1419256 0.1011741 0.0707868 0.0533034 0.0332994 0.0188676
CA8 CA9
0.0151044 0.0094876
```

EXTRACTING AXIS SCORES

To extract a range of scores from a fitted ordination use scores()

- takes an ordination object as the first argument
- · choices which axes? Defaults to c(1,2)
- display which type(s) of scores to return
 - "sites" or "wa": scores for samples in response matrix
 - "species": scores for variables/columns in response
 - "lc": linear combination site scores
 - "bp": biplot scores (coords of arrow tip)
 - "cn": centroid scores (coords of factor centroids)

9

EXTRACTING AXIS SCORES

SCALINGS...

When we draw the results of many ordinations we display 2 or more sets of data Can't display all of these and maintain relationships between the scores

Solution scale one set of scores relative to the other via the scaling argument

- scaling = 1 Focus on sites, scale site scores by λ_i
- scaling = 2 Focus on species, scale species scores by λ_i
- scaling = 3 Symmetric scaling, scale both scores by $\sqrt{\lambda_i}$
- \cdot scaling = -1 As above, but
- scaling = -2 For cca() multiply results by $\sqrt{(1/(1-\lambda_i))}$
- scaling = -3 this is Hill's scaling
- scaling < 0 For rda() divide species scores by species' σ
- scaling = 0 raw scores

scores(cca1, choices = 1:2, display = "species", scaling = 3)

10

PARTIAL CONSTRAINED ORDINATIONS

Partial constrained ordinations remove the effect of one or more variables then fit model of interest

Argument Z is used for a data frame of variables to partial out

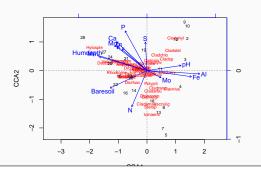

Or with the formula interface use the Condition() function

13

TRIPLOTS

Triplots will generally produce a mess; we can really only display a couple of bits approximately anyway Trying to cram three things in is a recipe for a mess... but we can do it

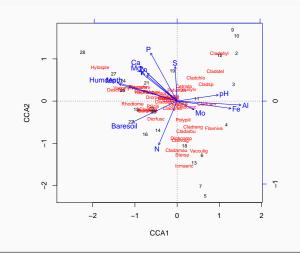

plot(cca1)

1/

TRIPLOTS

plot(cca1)

BUILDING CONSTRAINED ORDINATION MODELS

If we don't want to think it's easy to fit a poor model with many constraints

That's what we just did with cca1 and rda1

Remember, CCA and RDA are *just regression methods* — everything you know about regression applies here

A better approach is to *think* about the important variables and include only those

The formula interface allows you to create interaction or quadratic terms easily (though be careful with latter)

It also handles factor or class constraints automatically unlike the basic interface

BUILDING CONSTRAINED ORDINATION MODELS

```
vare.cca <- cca(varespec ~ Al + P*(K + Baresoil), data = varechem)</pre>
vare.cca
Call: cca(formula = varespec ~ Al + P * (K + Baresoil), data =
            Inertia Proportion Rank
Total
             2.083
                      1.000
Constrained 1.046
                     0.502
Unconstrained 1.038 0.498 17
Inertia is mean squared contingency coefficient
Eigenvalues for constrained axes:
 CCA1 CCA2 CCA3 CCA4 CCA5 CCA6
0.3756 0.2342 0.1407 0.1323 0.1068 0.0561
Eigenvalues for unconstrained axes:
   CA1 CA2 CA3 CA4 CA5 CA6 CA7
0.27577 0.15411 0.13536 0.11803 0.08887 0.05511 0.04919 0.03781
(Showed only 8 of all 17 unconstrained eigenvalues)
```

BUILDING CONSTRAINED ORDINATION MODELS

For CCA we have little choice but to do

- 1. Fit well-chosen set of candidate models & compare, or
- 2. Fit a *full* model of well-chosen variables & then do stepwise selection

But automatic approaches to model building should be used cautiously!

The standard step() function can be used as vegan provides two helper methods, deviance() and extractAIC(), used by step()

Vegan also provides methods for class "cca" for add1() and drop1()

10

VARIANCE INFLATION FACTORS

Linear dependencies between constraints can be investigated via the variance inflation factor or VIF

VIF is a measure of how much the variance of $\hat{\beta}_j$ is inflated by presence of other covariates

Lots of rules of thumb

- VIF >= 20 indicates strong collinearity in constraints
- · VIF >= 10 potnetially of concern & should be looked at

Computed via vif.cca()

STEPWISE SELECTION IN CCA

step() uses AIC which is a fudge for RDA/CCA. Alternatively use function ordistep()

- 1. Define an upper and lower model scope, say the full model and the null model
- 2. To step from the lower scope or null model we use

```
upr <- cca(varespec ~ ., data = varechem)
lwr <- cca(varespec ~ 1, data = varechem)
set.seed(1)
mods <- ordistep(lwr, scope = formula(upr), trace = 0)</pre>
```

trace = 0 is used her to turn off printing of progress

Permutation tests are used (more on these later); the theory for an AIC for ordination is somewhat loose

1

17

STEPWISE SELECTION IN CCA

The object returned by **step()** is a standard **"cca"** object with an extra component **\$anova**

The **\$anova** component contains a summary of the steps involved in automatic model building

```
Total 2.0832 1.0800 Constrained 0.6441 0.3992 3 Unconstrained 1.4391 0.6908 20 Inertia is mean squared contingency coefficient

Eigenvalues for constrained axes:
CCA1 CCA2 CCA3 0.3616 0.1700 0.1126

Eigenvalues for unconstrained axes:
CA1 CA2 CA3 CA4 CA5 CA6 CA7 CA8 0.3500 0.2201 0.1851 0.1551 0.1351 0.1003 0.0773 0.0537 (Showed only 8 of all 20 unconstrained eigenvalues)
```

STEPWISE SELECTION IN CCA

The **\$anova** component contains a summary of the steps involved in automatic model building

mods\$anova

```
Df AIC F Pr(>F)
+ Al 1 128.61 3.6749 0.005 **
+ P 1 127.91 2.5001 0.005 **
+ K 1 127.44 2.1688 0.035 *
---
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1
```

22

STEPWISE SELECTION IN CCA

Step-wise model selection is fairly fragile; if we start from the full model we won't end up with the same final model

```
mods2 <- step(upr, scope = list(lower = formula(lwr), upper = formula(upr)), trace = 0,</pre>
            test = "perm")
mods2
Call: cca(formula = varespec ~ P + K + Mg + S + Mn + Mo + Baresoil
+ Humdepth, data = varechem)

 CA10 CA11 CA12 CA13 CA14 CA15
0.01646 0.01364 0.00823 0.00655 0.00365 0.00238
```

ADJUSTED $\it r^2$ FOR $\it LINEAR$ MODELS

As with ordinary \mathbb{R}^2 , that of an RDA is biased for the same reasons as for a linear regression

- adding a variable to constraints will increase R^2
- \cdot the larger the number of constraints in the model the larger \mathbb{R}^2 is due to random correlations

Can attempt to account for this bias via an adjusted \mathbb{R}^2 measure

$$R_{adj}^2 = 1 - \frac{n-1}{n-m-1}(1-R^2)$$

- \cdot n is number of samples m is number of constraints (model degrees of freedom)
- Can be used up to $\sim M > n/2$ before becomes too conservative
- · Can be negative
- Compute using RsquareAdj()

23

STEPWISE SELECTION VIA ADJUSTED $\it r^2$

The problems with stepwise selection in regression models are myriad. Affects RDA, CCA, etc as well

Blanchet, Legendre, and Borcard (2008) proposed a two-step solution for models where R^2_{adi} makes sense

- · Global test of all constraints
 - · Proceed only if this test is significant
 - · Helps prevent inflation of overall type I error
- · Proceed with forward selection, but with two stopping rules
 - Usual significance threshold α
 - The global R_{adi}^2
 - · Stop if next candidate model is non-significant or if R_{adi}^2 exceeds the global R_{adi}^2

Available in ordiR2step()

25

PERMUTATION TESTS IN VEGAN

RDA has lots of theory behind it, CCA not as much. However, ecological/environmental data invariably violate what little theory we have

Instead we use permutation tests to assess the importance of fitted models — the data are shuffled in some way and the model refitted to derive a Null distribution under some hypothesis of $no\ effect$

PERMUTATION TESTS

PERMUTATION TESTS IN VEGAN

What is shuffled and how is of paramount importance for the test to be valid

- · No conditioning (partial) variables then rows of the species data are permuted
- With conditioning variables, two options are available, both of which *permute* residuals from model fits
 - The full model uses residuals from model $Y = X + Z + \varepsilon$
 - The reduced model uses residuals from model $Y = X + Z + \varepsilon$
- In vegan which is used can be set via argument model with "direct", "full", and "reduced" respectively
- In current vegan option method = "full" is disabled

27

PERMUTATION TESTS IN VEGAN

A test statistic is required, computed for observed model & each permuted model **vegan** uses a pseudo-F statistic

$$F = \frac{\chi_{model}^2 / df_{model}}{\chi_{resid}^2 / df_{resid}}$$

Evaluate whether F is unusually large relative to the null (permutation) distribution of F

PERMUTATION TESTS IN VEGAN: anova()

- The main user function is the anova() method
- It is an interface to the lower-level function permutest.cca()
- At its most simplest, the anova() method tests whether the "model" as a whole is significant

$$F = \frac{1.4415/14}{0.6417/9} = 1.4441$$

```
set.seed(42)
(perm <- anova(cca1))

Permutation test for cca under reduced model
Permutation: free
Number of permutations: 999

Model: cca(formula = varespec ~ N + P + K + Ca + Mg + S + Al + Fe + Mn + Zn + Mo + Baresoil + Humdepth + pH, data = varechem)

Df ChiSquare F Pr(>F)

Model 14 1.44148 1.4441 0.041 +

Residual 9 0 64171
```

30

PERMUTATION TESTS IN VEGAN: anova()

- anova() will continue permuting only as long as it is uncertain whether the the p-value is above or below the chosen threshold (say p=0.05)
- If the function is sure the permuted p is above the threshold anova() may return after only a few hundred permutations
- In other cases many hundreds or thousands of permutations may be required to say whether the model is above or below the threshold
- In the example, 1599 permutations were required

perm

PERMUTATION TESTS IN VEGAN: anova()

29

31

Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 ' ' 1

· anova.cca() has a number of arguments

```
function (object, ..., permutations = how(nperm = 999), by = NULL,
    model = c("reduced", "direct", "full"), parallel = getOption("mc.cores"),
    strata = NULL, cutoff = 1, scope = NULL)
```

- alpha is the desired p value threshold (Type I error rate)
- beta is the Type II error rate

args(anova.cca)

- · Permuting stops if the result is different from alpha for the given beta
- This is evaluated every **step** permutations
- perm.max sets a limit on the number of permutations
- by determines what is tested; the default is to test the model
- More direct control can be achieved via permutest.cca()

TYPES OF PERMUTATION TEST IN VEGAN

A number of types of test can be envisaged

- · Testing the overall significance of the model
- Testing constrained (canonical) axes
- · Testing individual model terms sequentially
- The marginal effect of a single variable

The first is the default in anova()

The other three can be selected via the argument method

PERMUTATION TESTS | TESTING CANONICAL AXES

- The constrained (canonical) axes can be individually tests by specifying by = "axis"
- The first axis is tested in terms of variance explained compared to residual variance
- The second axis is tested after partialling out the first axis... and so on

34

PERMUTATION TESTS | TESTING TERMS SEQUENTIALLY

- The individual terms in the model can be tested using by = "terms"
- The terms are assessed in the order they were specified in the model, sequentially from first to last
- Test is of the additional variance explained by adding the kth variable to the model
- · Ordering of the terms will affect the results

PERMUTATION TESTS | TESTING TERMS MARGINAL EFFECTS

- The marginal effect of a model term can be assessed using by = "margin"
- The marginal *effect* is the effect of a particular term when all other model terms are included in the model

33

35

CONSTRAINED ORDINATION WORKED EXAMPLE | SPRING MEADOW VEGETATION

Example & data taken from Leps & Smilauer, Case Study 2

Spring fen meadow vegetation in westernmost Carpathian mountains

```
## load vegan
library("vegan")

## load the data
spp <- read.csv("data/meadow-spp.csv", header = TRUE, row.names = 1)
env <- read.csv("data/meadow-env.csv", header = TRUE, row.names = 1)</pre>
```

37

39

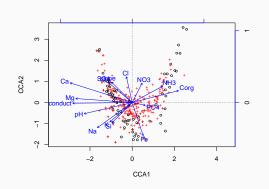

CONSTRAINED ORDINATION WORKED EXAMPLE | SPRING MEADOW VEGETATION

CCA a reasonable starting point as the gradient is long here (check with **decorana()** if you want)

38

DIAGNOSTICS FOR CONSTRAINED ORDINATIONS

vegan provides a series of diagnostics to help assess the model fit

- goodness()
- · inertcomp()
- spenvcor()
- · intersetcor()
- · vif.caa()

45

DIAGNOSTICS FOR CONSTRAINED ORDINATIONS | GOODNESS OF FIT

goodness() computes two goodness of fit statistics for species or sites
Which goodness of fit measure is returned is controlled by argument statistic

- statistic = "explained (default) gives the cumulative proportion of variance explained by each axis
- statistic = "distance" gives the residual distance between the "fitted" location in constrained ordination space and the location in the full dimensional space

DIAGNOSTICS FOR CONSTRAINED ORDINATIONS | GOODNESS OF FIT

```
head(goodness(mods))

CCA1 CCA2 CCA3

Callvulg 0.0062471656 0.318907619 0.8254657

Empenigr 0.1164701677 0.137604904 0.1953245

Rhodtome 0.0999089739 0.169697909 0.1824153

Vaccmyrt 0.2361482843 0.240516323 0.2406730

Vaccviti 0.1523704591 0.156502301 0.2110550

Pinusylv 0.0009244423 0.004802076 0.0060096

head(goodness(mods, summarize = TRUE))

Callvulg Empenigr Rhodtome Vaccmyrt Vaccviti Pinusylv 0.8254657 0.1953245 0.1824153 0.2406730 0.2110550 0.0060096
```

47

DIAGNOSTICS FOR CONSTRAINED ORDINATIONS | INERTIA DECOMPOSITION

inertcomp() decomposes the variance in samples or species in partial, constrained, and unconstrained components

Same two types of measure available by argument statistic

- statistic = "explained (default) gives the decomposition in terms of variance
- statistic = "distance" gives decomposition in terms of the the residual distance
- Can output as proportions of total via **proportion = TRUE**

```
head(inertcomp(mods, proportional = TRUE))

CCA CA
Callvulg 0.8254657 0.1745343
Empenigr 0.1953245 0.8046755
Rhodtome 0.1824153 0.8175847
Vaccmyrt 0.2406730 0.7593270
Vaccviti 0.2110550 0.7889450
Pinusylv 0.0060096 0.9939904
```

49

DIAGNOSTICS FOR CONSTRAINED ORDINATIONS | SPECIES-ENVIRONMENT CORRELATIONS

spenvcor() returns the species-environment correlation

The (weighted) correlation between the weighted average-based and the linear combination-based sets of site scores

A poor measure of goodness of fit. Sensitive to

- outliers (like all correlations)
- overfitting (using too many constraints)

Better models can have poorer species-environment correlations

spenvcor(mods)

CCA1 CCA2 CCA3
0.8554808 0.8132873 0.8792797

50

DIAGNOSTICS FOR CONSTRAINED ORDINATIONS | INTERSET CORRELATIONS

intersetcor() returns the interset correlations; the (weighted) correlation between
the weighted average-based site scores and each constraint variable

Another poor diagnostic

· correlation based

intersetcor(mods)

• focuses on a single constraint-axis combination at a time

Vector fitting (envfit()) or biplot scores (scores(model, display = "bp")) are
better alternatives

```

RESTRICTED PERMUTATION TESTS

RESTRICTED PERMUTATION TESTS

What is shuffled and how is of paramount importance for the test to be valid

Complete randomisation (default in **vegan**) assumes a null hypothesis where all observations are *independent*

Ecological / environmental data often aren't independent

- · Temporal or spatial correlation
- · Clustering, repeated measures
- Nested sampling designs (Split-plots designs)
- Blocks

٠ ..

Permutation *must* give null distribution of the test statistic whilst preserving the *dependence* between observations

Trick is to shuffle the data whilst preserving that dependence

RESTRICTED PERMUTATIONS

Canoco has had restricted permutations for a *long* time. **vegan** has only recently caught up & we're not (quite) there yet

vegan still only knows how to completely randomise data or completely randomise
within blocks (called strata in vegan)

The newish package **permute** grew out of initial code in the **vegan** repository to generate the sorts of restricted permutations available in Canoco

We have fully integrated permute into vegan...

vegan depends on **permute** so you should have it already installed & loaded when using **vegan**

54

RESTRICTED PERMUTATIONS WITH PERMUTE

permute follows Canoco closely — at the chiding of Cajo ter Braak when it didn't do what he wanted!

Samples can be thought of as belonging to three levels of a hierarchy

- the sample level; how are individual samples permuted
- $\boldsymbol{\cdot}$ the \emph{plot} level; how are samples grouped at an intermediate level
- \cdot the *block* level; how are samples grouped at the outermost level

Blocks define groups of plots, each of which can contain groups of samples

RESTRICTED PERMUTATIONS WITH PERMUTE

Blocks are *never* permuted; if defined, only plots or samples *within* the blocks get shuffled & samples never swapped between blocks

Plots or samples within plots, or both can be permuted following one of four simple permutation types

- 1. Free permutation (randomisation)
- 2. Time series or linear transect, equal spacing
- 3. Spatial grid designs, equal regular spacing
- 4. Permutation of plots (groups of samples)
- 5. Fixed (no permutation)

Multiple plots per block, multiple samples per plot; plots could be arranged in a spatial grid and samples within each of the plots form a time series

55

RESTRICTED PERMUTATIONS WITH PERMUTE | BLOCKS

Blocks are a random factor that does not interact with factors that vary within blocks

Blocks form groups of samples that are never permuted between blocks, only within blocks

Using blocks you can achieve what the **strata** argument does now in **vegan**; needs to be a factor variable

The variation *between* blocks should be excluded from the test; **permute** doesn't do this for you!

Use + Condition(blocks) in the model formula where blocks is a factor containing the block membership for each observation

RESTRICTED PERMUTATIONS WITH PERMUTE | TIME SERIES & LINEAR TRANSECTS

Can link *randomly* starting point of one series to any time point of another series if series are stationary under null hypothesis that the series are unrelated

Achieve this via cyclic shift permutations — wrap series into a circle by joining start and end points

Works OK if there are no trends or cyclic pattern — autocorrelation structure only broken at the end points *if* series are stationary

Can detrend to make series stationary but not if you want to test significance of a trend

shuffle(10, control = how(within = Within(type = "series")))

[1] 9 10 1 2 3 4 5 6 7 8

5

RESTRICTED PERMUTATIONS WITH PERMUTE | SPATIAL GRIDS

- The trick of cyclic shifts can be extended to two dimensions for a regular spatial grid arrangement of points
 - Now shifts are toroidal as we join the end point in the x direction together and in the y direction together

```
matrix(perm, ncol = 3)
```

	[,1]	[,2]	[,3]
[1,]	6	9	3
[2,]	4	7	1
[3.]	5	8	2

RESTRICTED PERMUTATIONS WITH PERMUTE | WHOLE-PLOTS & SPLIT-PLOTS I

Split-plot designs are hierarchical with two levels of units

- 1. whole-plots, which contain
- 2. **split-plots** (the samples)

Can permute one or both of these but whole-plots must be of equal size

Essentially allows more than one error stratum to be anlyzed

Test effect of constraints that vary *between* whole plots by permuting the whole-plots whilst retaining order of split-splots (samples) within the whole-plots

Test effect of constraints that vary within whole-plots by permuting the split-plots within whole-plots without permuting the whole-plots

59

57

RESTRICTED PERMUTATIONS WITH PERMUTE | WHOLE-PLOTS & SPLIT-PLOTS II

Whole-plots or split-plots can be time series, linear transects or rectangular grids in which case the appropriate restricted permutation is used

If the split-plots are parallel time series & time is an autocorrelated error component affecting all series then the same cyclic shift can be applied to each time series (within each whole-plot) (constant = TRUE)

RESTRICTED PERMUTATIONS WITH PERMUTE | MIRRORING

(Without wanting to get *too* technical) Mirroring in restricted permutations allows for isotropy in dependences by reflecting the ordering of samples in time or spatial dimensions

For a linear transect, technically the autocorrelation at lag h is equal to that at lag -h (also in a trend-free time series)

Hence the series (1, 2, 3, 4) and (4, 3, 2, 1) are equivalent from this point of view & we can draw permutations from either version

Similar argument can be made for spatial grids

Using mirror = TRUE then can double (time series, linear transects) or quadruple (spatial grids) the size of the set of permutations

61

RESTRICTED PERMUTATIONS WITH PERMUTE | THE SET OF PERMUTATIONS

Using restricted permutations can severely reduce the size of the set of allowed permutations

As the minimum p value obtaininable is 1/np where np is number of allowed permutations (including the observed) this can impact the ability to detect signal/pattern

If we don't want mirroring

- in a time series of 20 samples the minimum p is 1/20 (0.05)
- in a time series of 100 samples the minimum p is 1/100 (0.01)
- in a data set with 10 time series each of 20 observations (200 total), if we assume an autocorrelated error component over all series (constant = TRUE) then there are only 20 permutations of the data and minimum p is 0.05

When the set of permutations is small it is better to switch to an exact test & evaluate all permutations in the set rather than randomly sample from the set

RESTRICTED PERMUTATIONS WITH PERMUTE | DESIGNING PERMUTATION SCHEMES

In permute, we set up a permutation scheme with how()

We sample from the permutation scheme with

- \cdot shuffle(), which gives a single draw from scheme, or
- \cdot shuffleSet(), which returns a set of n draws from the scheme

allPerms() can generated the entire set of permutations — note this was designed for small sets of permutations & is slow if you request it for a scheme with many thousands of permutations!

RESTRICTED PERMUTATIONS WITH PERMUTE | DESIGNING PERMUTATION SCHEMES

how() has three main arguments

- 1. within takes input from helper Within()
- 2. plots takes input from helper Plots()
- 3. **blocks** takes a factor variable as input

```
plt <- gl(3, 10)
h <- how(within = Within(type = "series"), plots = Plots(strata = plt))</pre>
```

65

RESTRICTED PERMUTATIONS WITH PERMUTE | DESIGNING PERMUTATION SCHEMES

how() has additional arguments, many of which control the heuristics that kick in to stop you shooting yourself in the foot and demanding 9999 permutations when there are only 10

- \cdot complete should we enumerate the entire set of permutations?
- minperm lower bound on the size of the set of permutations at & below which we turn on complete enumeration

```
function (within = Within(), plots = Plots(), blocks = NULL,
    nperm = 199, complete = FALSE, maxperm = 9999, minperm = 99,
    all.perms = NULL, make = TRUE, observed = FALSE)
NULL
```

RESTRICTED PERMUTATIONS WITH PERMUTE | DESIGNING PERMUTATION SCHEMES

Helper functions make it easy to change one or a few aspects of permutation scheme, rest left at defaults

```
args(Within)

function (type = c("free", "series", "grid", "none"), constant = FALSE,
    mirror = FALSE, ncol = NULL, nrow = NULL)

NULL

args(Plots)

function (strata = NULL, type = c("none", "free", "series", "grid"),
    mirror = FALSE, ncol = NULL, nrow = NULL)

NULL
```

66

RESTRICTED PERMUTATIONS WITH PERMUTE | TIME SERIES EXAMPLE I

Time series within 3 plots, 10 observation each

67

RESTRICTED PERMUTATIONS WITH PERMUTE | TIME SERIES EXAMPLE II

Time series within 3 plots, 10 observation each, same permutation within each
